secondauthor@i2.org

## Abstract

*This paper presents FinGPT Trader, a novel confidence-weighted sentiment analysis system designed to democratize quantitative trading in African markets. The project addresses significant barriers to entry, including expensive infrastructure, limited technical expertise, and restricted access to sophisticated trading tools. By leveraging a fine-tuned Falcon-7B Large Language Model for financial sentiment analysis and integrating it with lightweight technical analysis, FinGPT Trader offers a resource-efficient solution tailored for environments with constrained resources. Preliminary results indicate significant improvements in accessibility and cost-effectiveness compared to traditional trading platforms. This approach has the potential to unlock quantitative trading opportunities for Small and Medium-sized Enterprises (SMEs), retail investors, and emerging fund managers across Africa, fostering greater financial inclusion and economic development in the region.*

## 1. Introduction

### 1.1. The African Financial Markets Landscape

African financial markets are undergoing a significant transformation, characterized by rapid technological adoption and evolving investment landscapes. A key driver of this change is the burgeoning adoption of cryptocurrencies across the continent. Countries like Nigeria, Kenya, and South Africa are leading global cryptocurrency adoption, with a substantial volume of on-chain transactions [10, 1]. This surge is partly fueled by the mobile money revolution, exemplified by platforms such as M-Pesa and Airtel Money, which have created new avenues for financial transactions and, consequently, trading opportunities [2, 19]. Sub-Saharan Africa, in particular, has emerged as a global leader in mobile money, accounting for a significant portion of worldwide mobile money accounts and transaction values [3, 20]. Despite these advancements, African markets

still face challenges, notably a lack of institutional trading infrastructure comparable to more developed markets and the prohibitive costs associated with traditional trading platforms like Bloomberg and Reuters terminals.

### 1.2. The Quantitative Trading Divide

Quantitative trading, characterized by the use of mathematical models and automated systems to execute trades, has traditionally been dominated by well-capitalized institutions in developed markets [15]. The barriers to entry are substantial, including the need for complex mathematical models often requiring PhD-level expertise, expensive data feeds, and robust infrastructure [24]. Access to sophisticated sentiment analysis tools, crucial for interpreting market sentiment from news and social media, has also been limited to a select few. In the African context, these challenges are compounded by specific regional hurdles. Internet connectivity can be intermittent, local financial data sources are often scarce, and regulatory frameworks vary significantly across different countries, adding layers of complexity [9]. Furthermore, there is a notable skills gap in quantitative finance within many African nations, making it difficult for local talent to engage in this specialized field [17].

### 1.3. The Promise of Large Language Models

The advent of Large Language Models (LLMs) has ushered in a new era for financial analysis, particularly in the realm of sentiment analysis. Recent advancements in financial Natural Language Processing (NLP), such as FinBERT and the broader FinGPT initiative, have demonstrated the capability of these models to process and interpret vast amounts of unstructured financial text data [5, 18]. The open-source nature of many of these models holds significant democratization potential, making advanced analytical capabilities more accessible to a wider audience. This technology offers a cost-effective solution for sentiment analysis, enabling the extraction of valuable insights from financial news and reports without the need for pro-

hibitively expensive proprietary systems [4]. The FinGPT project, in particular, emphasizes a data-centric approach and lightweight adaptation, making it suitable for deployment in diverse environments, including those with limited computational resources [28].

## 2. Related Work

### 2.1. Financial Sentiment Analysis

Financial sentiment analysis (FSA) has evolved significantly from traditional lexiconbased approaches to sophisticated deep learning models. Early methods relied on predefined dictionaries of positive and negative words to gauge sentiment from financial texts. However, these approaches often struggled with the nuanced and domain-specific language of finance, leading to limited accuracy [6]. The advent of deep learning, particularly transformer-based models like BERT, revolutionized NLP and subsequently FSA. Models such as FinBERT, a BERT variant fine-tuned on large corpora of financial texts, demonstrated superior performance in capturing financial sentiment by understanding contextual nuances and domain-specific terminology [12]. More recently, the FinGPT initiative has pushed the boundaries further by developing open-source large language models specifically designed for the financial sector. These models, often leveraging instruction tuning and data-centric approaches, aim to provide accessible and powerful tools for financial sentiment analysis, capable of processing internet-scale financial data [13, 27]. The FinGPT Trader project builds upon this foundation by integrating a fine-tuned Falcon-7B model for sentiment analysis, emphasizing the importance of confidence-weighted scoring to enhance signal reliability.

### 2.2. Quantitative Trading Systems

Quantitative trading systems are automated frameworks that execute trading strategies based on mathematical models and algorithms. These systems typically involve signal generation, portfolio optimization, and robust risk management components [8]. Signal generation, the core of any quantitative trading system, often relies on technical indicators, statistical arbitrage, or, increasingly, sentiment analysis derived from financial news and social media [25]. Risk management in algorithmic trading is crucial, encompassing aspects like position sizing, exposure monitoring, and value-at-risk (VaR) calculations to mitigate potential losses [7]. The FinGPT Trader project integrates these elements by combining sentiment-driven signals with technical market analysis and basic risk management features. The project's emphasis on confidence-weighted sentiment scoring and adaptive correlation tracking aims to refine signal generation, addressing the inherent noise and volatility often found in financial markets, particularly in emerging

economies.

### 2.3. AI for Financial Inclusion in Africa

Financial inclusion remains a critical development goal in Africa, where a significant portion of the population remains unbanked or underserved by traditional financial institutions. Artificial intelligence (AI) is emerging as a powerful enabler for deepening financial inclusion across the continent [26]. AI-powered fintech solutions are being deployed to simplify access to credit, assess risks for individuals without traditional credit histories, and customize financial services [14, 22]. Examples include platforms like Tala and Branch, which leverage AI to offer microloans, and initiatives like Periculum, which uses AI and alternative data to expand credit access [21, 11]. Mobile banking, already a widespread phenomenon in Africa, is further enhanced by AI through chatbots and other intelligent applications that improve accessibility and user experience [23, 16]. The FinGPT Trader project aligns with this broader trend by aiming to democratize access to sophisticated trading tools, thereby empowering a wider segment of the African population, including SMEs and retail investors, to participate in quantitative finance. This contributes to financial literacy and fosters an opensource ecosystem for local fintech development.

## 3. System Architecture

### 3.1. Core Components Overview

**The FinGPT Trader system** is designed as a comprehensive quantitative trading platform that processes financial news and market data in parallel to identify and act on potential trading opportunities. Its architecture is modular, allowing for distinct functionalities to operate cohesively. The core components and their interactions are visualized in Figure 1.

At a high level, news data is fed into the Falcon-7B sentiment analysis module, which, after confidence weighting, generates sentiment-based signals. Concurrently, market data undergoes technical analysis to detect market inefficiencies. Both types of signals converge at the Trading Engine, which then initiates order execution through Binance integration, with continuous portfolio tracking and risk management oversight. This event-driven architecture ensures asynchronous processing of market events, crucial for responsiveness in dynamic trading environments.

### 3.2. The Confidence-Weighted Sentiment Innovation

A significant challenge in leveraging sentiment analysis for trading is the inherent noise and potential unreliability of raw sentiment scores. To address this, FinGPT Trader introduces a novel confidence-weighted sentiment scoring

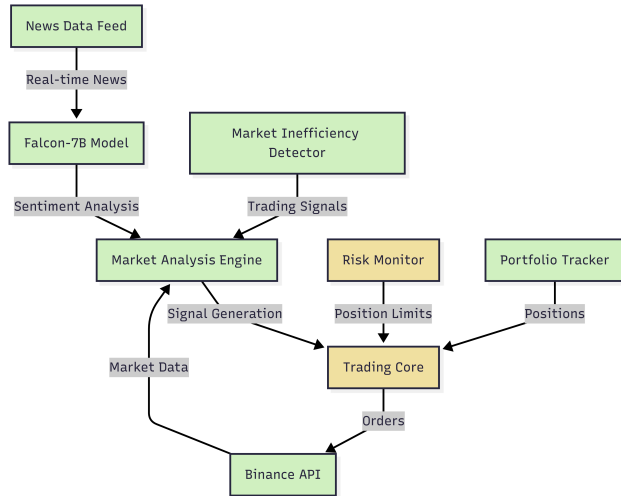

Figure 1. The system architecture of FinGPT Trader, showing the flow of data from news and market sources through analysis, signal generation, and execution.

mechanism. Instead of directly using the sentiment score, the system combines the model’s confidence in its prediction with the absolute strength of the sentiment. The formula applied is:

$$\text{weighted\_score} = (\text{confidence} * 0.6) * (\text{abs}(\text{sentiment\_score}) * 0.4)$$

This approach assigns a higher weight (60%) to the model’s confidence and a slightly lower weight (40%) to the sentiment’s absolute strength. The primary benefit of this weighting is its ability to filter out low-confidence predictions, thereby significantly reducing false signals that could lead to erroneous trading decisions. This innovation is particularly valuable in the African context, where financial news sources may be less structured or diverse, and the reliability of sentiment extraction can vary. By prioritizing high-confidence signals, the system enhances the robustness and trustworthiness of its trading recommendations.

### 3.3. Adaptive Correlation Tracking

Market dynamics, especially in emerging markets, are subject to rapid shifts and unique local influences. To account for varying market conditions and the evolving relationship between sentiment and price movements, FinGPT Trader incorporates an adaptive correlation tracking mechanism. The system continuously maintains a history of sentiment and price changes, calculating correlation coefficients between them. This dynamic adjustment based on historical sentiment-price relationships allows the system to adapt its signal strength and position sizing strategies in volatile markets. For instance, if a strong positive sentiment signal historically leads to a significant price increase in a particular asset, the system can leverage this correlation for more

aggressive position sizing. Conversely, if the correlation weakens or turns negative, the system can adjust its strategy to be more conservative. This adaptive approach is crucial for navigating the diverse and often unpredictable market conditions prevalent across African exchanges, enhancing the system’s ability to generate reliable trading signals.

### 3.4. Resource-Efficient Design

One of the primary objectives of FinGPT Trader is to provide a solution that is accessible and operable even in resource-constrained environments, which is a common characteristic in many African markets. This is achieved through several design choices focused on computational efficiency. Firstly, the project leverages *llama.cpp* for efficient inference of the Falcon-7B model. *llama.cpp* is known for its ability to run large language models with minimal computational resources, making it feasible to deploy the sentiment analysis component on hardware with as little as 8GB of RAM, typical of a standard business laptop. This significantly reduces the hardware barrier to entry. Secondly, the system is designed to minimize expensive API calls, optimizing data retrieval and processing to reduce operational costs. Lastly, the asynchronous processing architecture, powered by *Python’s AsyncIO framework*, enables the system to handle multiple data streams concurrently and efficiently. This ensures that the system can process real-time market data and news feeds without significant latency, even with limited computational power, thereby maximizing its responsiveness and effectiveness in dynamic trading environments.

## 4. Democratization Features

### 4.1. Low Barrier to Entry

FinGPT Trader is specifically engineered to lower the traditional barriers to entry for quantitative trading, making it accessible to a broader audience beyond institutional investors. The technical complexity, often a deterrent for new entrants, is significantly reduced through simplified configuration mechanisms, primarily utilizing hierarchical YAML files. This abstraction allows users to define trading parameters and strategies without deep programming knowledge. The cost structure represents a radical departure from conventional quantitative trading setups. Traditional platforms, such as Bloomberg terminals and associated infrastructure, can incur annual costs ranging from 50,000 to over 100,000. In stark contrast, FinGPT Trader aims for an annual operational cost of less than \$1,000 primarily covering API costs and cloud computing resources. This drastic reduction in financial outlay makes sophisticated trading tools attainable for Small and Medium-sized Enterprises (SMEs) and individual investors. Furthermore, while traditional quantitative finance often demands PhD-level exper-

tise in complex mathematical modeling, FinGPT Trader is designed to be operable with basic Python knowledge, significantly broadening the pool of potential users and fostering a more inclusive trading environment.

## 4.2. African Market Adaptations

Recognizing the unique operational environment of African markets, FinGPT Trader incorporates several adaptations to ensure its effectiveness and resilience. Internet connectivity in many parts of Africa can be intermittent or unreliable. The system is designed with connectivity resilience in mind, employing asynchronous processing and robust error handling to manage temporary disconnections and data inconsistencies, ensuring continuous operation even under challenging network conditions. Furthermore, the system prioritizes integration with accessible and widely used platforms, focusing on major cryptocurrency exchanges like Binance, which have significant presence and liquidity in African markets, and planning for future integration with local exchanges. Regulatory landscapes across African countries are diverse and constantly evolving, particularly concerning cryptocurrencies. FinGPT Trader is designed with configurable compliance parameters, allowing users to adapt the system to specific national regulations and reporting requirements. This flexibility is crucial for navigating the complex legal frameworks and ensuring adherence to local laws. Looking ahead, the project aims to extend language support to include major local African languages such as Swahili, Hausa, and Amharic. This multilingual capability will enable the system to process and analyze financial news and information from a wider array of local sources, providing more comprehensive and culturally relevant sentiment analysis for diverse African markets.

## 4.3. Educational Value

Beyond its direct utility as a trading system, FinGPT Trader also serves as a valuable educational tool, fostering financial literacy and quantitative trading concepts among its users. The system's transparent logic, particularly in its signal generation process, allows users to understand how sentiment and technical indicators translate into trading decisions. This clarity demystifies complex algorithmic trading strategies, making them more comprehensible to individuals without a deep background in quantitative finance. By providing a practical, hands-on platform, FinGPT Trader enables users to learn by doing, experimenting with different parameters and observing their impact on trading outcomes. This experiential learning approach is highly effective in building practical skills and theoretical understanding. Furthermore, the project's open-source nature cultivates a collaborative community where users can share knowledge, contribute to the system's de-

velopment, and collectively advance their understanding of quantitative trading. This community-driven approach not only enhances the system's capabilities but also creates a supportive environment for learning and skill development, contributing to the growth of quantitative finance expertise within African communities.

## 5. Implementation and Evaluation

### 5.1. Technical Implementation

The development of FinGPT Trader involved overcoming several technical challenges inherent in building a robust quantitative trading system, particularly one designed for emerging markets. A significant hurdle was addressing API parameter mismatches, especially during the integration with the Binance exchange. This required meticulous debugging and adaptation of the client initialization parameters to ensure seamless communication and data exchange. Another critical aspect was handling Unicode encoding for diverse news sources. Financial news from various African regions can come in different encodings, and proper handling was essential to prevent data corruption and ensure accurate sentiment analysis. The asynchronous processing complexities, while offering significant performance benefits, also presented challenges in managing concurrent data streams and ensuring proper synchronization. Finally, accurate calculation of minimum order sizes was crucial to prevent failed trades and optimize position sizing, requiring careful validation against exchange requirements.

### 5.2. Performance Requirements

To evaluate the effectiveness of FinGPT Trader, a comprehensive set of performance metrics will be employed, encompassing both trading efficacy and computational efficiency. Backtesting will be conducted on historical market data, particularly focusing on cryptocurrency pairs and currency pairs relevant to African markets (e.g., USD/ZAR, USD/NGN, USD/KES). Key performance indicators for trading efficacy will include: Sharpe ratio, to assess risk-adjusted returns; maximum drawdown, to measure the largest peak-to-trough decline in the portfolio; and overall profitability compared to a simple buy-and-hold strategy. Signal quality will be evaluated using precision and recall metrics for sentiment-driven signals, determining how accurately positive and negative sentiment translates into profitable trading opportunities. Computational efficiency will be measured by processing time for sentiment analysis and signal generation, as well as memory usage, to ensure the system remains lightweight and suitable for resource-constrained environments. These metrics will provide a quantitative assessment of the system's ability to generate profitable signals while managing risk and operating efficiently.

### 5.3. Cost-Benefit Analysis

A critical aspect of democratizing quantitative trading is demonstrating a clear cost-benefit advantage over traditional methods. A detailed cost-benefit analysis will compare the infrastructure and operational costs of FinGPT Trader against conventional quantitative trading setups. As previously highlighted, traditional setups can involve annual expenditures well into five or six figures, encompassing data subscriptions, high-performance computing, and specialized software licenses. In contrast, FinGPT Trader, by leveraging open-source models, efficient inference techniques like llama.cpp, and cloud-based resources, significantly reduces these costs, aiming for an annual expenditure of less than \$1,000. This substantial cost reduction is a primary benefit, making sophisticated trading strategies accessible to a much wider demographic. Beyond direct financial costs, the analysis will also consider accessibility metrics, such as setup time and technical requirements. The simplified configuration and lower hardware demands of FinGPT Trader translate into a faster and less technically demanding onboarding process, further reducing the implicit costs associated with specialized expertise and prolonged setup times. Performance comparisons, including returns versus a passive buy-and-hold strategy, will quantify the financial benefits derived from the system's trading signals, providing a holistic view of its value proposition.

### 5.4. African Market Case Studies

To validate the practical applicability and effectiveness of FinGPT Trader within the African context, specific case studies will be conducted across various market segments. These studies will focus on:

- (i) **Cryptocurrency Markets:** Analyzing the system's performance in trading major cryptocurrencies like Bitcoin and Ethereum on prominent African exchanges. This will involve assessing how well the sentiment analysis captures market sentiment from African crypto news sources and its impact on trading decisions.
- (ii) **Currency Pairs:** Investigating the system's utility in trading key African currency pairs against major global currencies, such as USD/ZAR (South African Rand), USD/NGN (Nigerian Naira), and USD/KES (Kenyan Shilling). This will highlight the system's adaptability to different liquidity profiles and market structures.
- (iii) **News Sources:** A crucial element will be to evaluate the impact of African financial news on trading signals. This involves analyzing how sentiment derived from local news outlets and financial publications influences the system's predictions and subsequent trad-

ing outcomes. These case studies will provide empirical evidence of FinGPT Trader's performance, its ability to navigate the unique challenges of African markets, and its potential to contribute to financial inclusion and economic growth in the region.

## 6. Challenges and Limitations

### 6.1. Technical Challenges

Despite its innovative approach, FinGPT Trader faces several technical challenges that are common in the development of sophisticated AI-driven trading systems. One significant challenge is **data quality**. The effectiveness of sentiment analysis heavily relies on the consistency and reliability of news sources and market data. Inconsistent data formats, missing information, or delayed feeds can compromise the accuracy of sentiment scores and technical indicators, leading to suboptimal trading decisions. Another limitation stems from **model limitations**, specifically the performance of the Falcon-7B model on highly specialized financial text. While fine-tuned, the model may still encounter difficulties in interpreting highly nuanced financial jargon, sarcasm, or complex economic reports, potentially leading to misinterpretations of market sentiment. **Latency issues** also pose a challenge; while the system is designed for asynchronous processing, achieving true real-time processing in high-frequency trading scenarios remains a complex task, especially when integrating multiple APIs and data sources. The **integration complexity** itself, involving various APIs for market data, news feeds, and exchange execution, introduces points of failure and requires robust error handling mechanisms to ensure system stability and reliability.

### 6.2. African-Specific Challenges

The deployment of FinGPT Trader in African markets introduces a unique set of challenges beyond the general technical hurdles.

**Regulatory uncertainty** is a prominent concern, as cryptocurrency regulations vary significantly across different African countries and are often in a nascent or evolving state. This fragmented regulatory landscape necessitates continuous monitoring and adaptation of the system to ensure compliance, which can be resource-intensive.

**Market liquidity** is another critical factor; while major cryptocurrencies may have sufficient liquidity on large exchanges, trading in some local assets or less popular pairs might suffer from low trading volumes, making it difficult to execute large orders without significant price impact.

**Infrastructure dependencies**, such as reliable internet connectivity and consistent power supply, are not uniformly guaranteed across the continent. Intermittent access to these basic utilities can disrupt the system's operation and data

flow, impacting its real-time capabilities.

Finally, **local expertise** in quantitative finance and AI is still developing in many regions. This necessitates significant training and support requirements for users to effectively utilize and maintain the FinGPT Trader system, posing a challenge for widespread adoption and independent operation.

### 6.3. Risk Considerations

Quantitative trading, by its nature, involves inherent risks that must be carefully considered. **Model bias** is a significant concern, particularly in sentiment analysis. The Falcon-7B model, even after fine-tuning, may exhibit biases present in its training data, leading to skewed sentiment interpretations. This can result in the system consistently misinterpreting certain financial news or market events, leading to suboptimal or even detrimental trading decisions.

**Overfitting** is another critical risk, where the model becomes too adapted to specific historical market conditions, performing poorly when market dynamics shift. This necessitates continuous monitoring, re-evaluation, and potential retraining of the model to maintain its efficacy.

**Regulatory compliance**, beyond the general uncertainty, involves specific requirements such as Know Your Customer (KYC) and Anti-Money Laundering (AML) regulations. While FinGPT Trader aims to be configurable, ensuring full compliance across diverse jurisdictions remains a complex operational challenge.

Lastly, **operational risks** are ever-present, including system failures, API outages from exchanges or data providers, and cybersecurity threats. Robust error handling, redundancy measures, and continuous monitoring are essential to mitigate these risks and ensure the system's stability and security.

## 7. Future Work

### 7.1. Technical Enhancements

The future development of FinGPT Trader will focus on several technical enhancements to improve its robustness, sophistication, and performance. **Advanced risk management** capabilities are a key priority, including the implementation of Value-at-Risk (VaR) calculations and correlation-aware metrics. This will allow for a more comprehensive assessment of portfolio risk and enable more nuanced risk-adjusted position sizing. Expanding beyond cryptocurrencies, the system will aim for **multi-asset support**, incorporating stocks, bonds, and commodities, which will broaden its applicability across diverse financial markets. To further enhance signal generation and prediction accuracy, **ensemble methods** will be explored, combining multiple models (e.g., different LLMs, traditional econometric models) to leverage their collective strengths and

mitigate individual weaknesses. Finally, **real-time optimization** techniques will be developed to allow for dynamic parameter adjustment based on live market conditions, ensuring the system remains adaptive and efficient in rapidly changing environments.

### 7.2. African Market Expansion

To maximize its impact on financial inclusion in Africa, FinGPT Trader will pursue significant expansion within the continent. This includes **local exchange integration** with prominent African stock exchanges such as the JSE (Johannesburg Stock Exchange), NSE (Nigerian Stock Exchange), and EGX (Egyptian Exchange). Such integrations will enable direct participation in local equity and bond markets, catering to a wider range of investment preferences. Further, **mobile money integration** with platforms like M-Pesa and Airtel Money APIs will facilitate seamless funding and withdrawal processes, leveraging the widespread adoption of mobile money across Africa. This will significantly lower the transactional barriers for individuals and SMEs. To address the linguistic diversity of the continent, **multi-lingual support** will be developed for sentiment analysis, initially focusing on major African languages like Swahili, Hausa, and Amharic. This will allow the system to process and derive sentiment from local news and social media, providing more accurate and relevant insights. Finally, continuous efforts will be made towards **regulatory compliance**, adapting the system to country-specific regulations and collaborating with local authorities to ensure legal and ethical operation across diverse African jurisdictions.

### 7.3. Community and Education

Building a sustainable ecosystem around FinGPT Trader necessitates a strong focus on community engagement and education. This includes developing **training programs** and workshops for African financial professionals, entrepreneurs, and students, equipping them with the necessary skills to utilize and contribute to the platform. Establishing **university partnerships** will foster academic collaboration and research, encouraging the next generation of quantitative finance and AI experts in Africa. The open-source nature of the project will be leveraged to build a vibrant **open-source** ecosystem, including a plugin architecture that allows developers to extend the system's functionalities and contribute new strategies or integrations. Finally, **mentorship programs** will be established to support local fintech development, connecting experienced professionals with aspiring innovators, thereby accelerating the growth of a self-sustaining quantitative finance community in Africa.

## 8. Conclusion

### 8.1. Key Contributions

This paper introduces FinGPT Trader, a pioneering quantitative trading system designed to address the significant barriers to entry in African financial markets. Our key contributions are multifaceted.

Firstly, we demonstrate a clear path towards the **democratization of quantitative trading**, making sophisticated tools accessible to Small and Medium-sized Enterprises (SMEs), retail investors, and emerging fund managers in Africa. This is achieved through a resource-efficient design and a substantially lower cost structure compared to traditional platforms. Secondly, we present a novel **technical innovation** in the form of a confidence-weighted sentiment analysis mechanism. This approach, which combines the Falcon-7B Large Language Model with a weighted scoring system, significantly enhances the reliability of trading signals by filtering out low-confidence predictions, a crucial feature in potentially less structured data environments.

Thirdly, the project emphasizes **practical impact** by incorporating African-specific adaptations, such as connectivity resilience and configurable compliance parameters, ensuring real-world applicability and effectiveness. Finally, our **open-source approach** fosters community-driven development, encouraging collaboration and knowledge sharing, which is vital for building a sustainable fintech ecosystem in Africa.

### 8.2. Broader Impact

The implications of FinGPT Trader extend beyond its immediate utility as a trading system, promising a broader transformative impact on the African financial landscape. By expanding access to sophisticated trading tools, the project directly contributes to **financial inclusion**, empowering individuals and businesses that have historically been excluded from advanced financial markets. This increased participation can stimulate **economic development** by fostering a more dynamic and efficient financial ecosystem.

The open-source nature and educational focus of FinGPT Trader facilitate **knowledge transfer**, building local quantitative finance expertise and reducing reliance on external, often expensive, solutions. This cultivates a self-sufficient and innovative environment within Africa.

Ultimately, FinGPT Trader serves as an **innovation catalyst**, inspiring further applications of artificial intelligence in finance and other sectors across the continent, driving technological advancement and economic growth from within.

### 8.3. Call to Action

To fully realize the potential of FinGPT Trader and its vision for democratizing quantitative trading in Africa, we

issue a call to action for various stakeholders. We seek **collaboration opportunities** with African exchanges, financial institutions, and regulatory bodies to facilitate seamless integration and ensure compliance with local market requirements. We invite **investment potential** from venture capitalists, impact investors, and development organizations to support the growth of local fintech startups leveraging this technology. Furthermore, we encourage engagement in **policy implications** discussions to shape regulatory frameworks that foster innovation while ensuring market stability and investor protection. Finally, we advocate for continued **research directions** through academic-industry collaboration, exploring new AI models, data sources, and trading strategies tailored to the unique characteristics of African markets. Through collective effort, we can unlock the full potential of AI to drive financial inclusion and economic prosperity across Africa.
